Parametric Hierarchy Recovery in Layout Extracted Netlists (Type Mapping)

John Lee
Puneet Gupta
DFM&Y 2011
Hierarchy Degradation

- Layout-Dependent Device Parameters
  - Stress effects
  - Lithography effects
  - Parasitics

- Added to each transistor
  - Breaks the hierarchy

Difficulties from flattened netlists

• Verification and analysis tools suffer from the lack of hierarchy:
  – Increases runtimes
  – Difficult to find common source of multiple errors
    • May have millions of errors from a single standard cell
    • Errors may be related to a repeating hierarchical block
  – Difficult to analyze
    • Too much information
Redundant layout dependent contexts

Most designs have redundant contexts:

- Multicore designs
- DSP designs
Hierarchy recovery using Type-Mapping

- Create **type-variants** to recover hierarchy
  - Tolerance based clustering:
    - Cluster device parameters if they are within a tolerance
  - Variants on the original hierarchical blocks
  - Capture the different layout contexts in a design

Hierarchical Type-Mapping

Type-Map “C”: Induced clusters can be merged
Type-Mapping Steps

• Start at the top of the hierarchy
  1. Cluster the clusters that are induced by higher level parent types
  2. Merge clusters that meet tolerance constraints
  3. Add free instances to existing clusters, if possible
    • Otherwise, create new clusters
Hierarchical Type-Mapping

Type-Map “C”: Induced clusters can be merged
Applications: Verification

- 5 real Industrial designs
  - Test0: 17M transistors
  - Test1: 834K transistors
  - Test2: 3.3M transistors (4 test1 cores)
  - Test3: 7.5M transistors (9 test1 cores)
  - Test4: 2.4M transistors
Applications: Verification

- 5 real Industrial designs (800k – 17M transistors)
- Comparison with Calibre: LVS & ERC
  - Runtime improvement vs. spread tolerance
    - Tolerance is a function of *maximum parameter deviation*
    - 1.0 – runtime for layout extracted netlist
Lithography effects and Timing Mismatch

- Static analysis flows based on standard cell abstraction
  - One cell is 2-100 transistors
  - Timing/power views stored in pre-characterized “.lib” files
- State of art 45nm logic designs have 10M+ cells and 50M+ transistors → Hierarchy preservation essential
Application: Timing

- ISCAS `89 designs + Open Cores ALU + 45nm Library
- Create type variants of standard cells
  - Post-lithography extracted netlist
  - Variations in L & W, tolerance a function of the nominal values
  - Map layout extracted cells onto standard cells
    - E.g. NAND_X1_VARIANT1, NAND_X1_VARIANT2, etc.

*estimated using Synopsys NanoTime
Application: Timing + Slack

- Type-variant library characterization too slow
  - 11 to 97 hrs

- Use slacks to adjust tolerances:
  - *Delay can increase by \( Y/T \) before path is critical*
  - Increase the tolerance by \( \frac{Y}{\alpha T} \rightarrow \text{reduce variant library size} \)

*estimated using Synopsys NanoTime*
Summary

- Created a method to recover hierarchy in post-layout designs
  - Creates type-variants of the original cells / blocks
  - Uses hierarchical type-mapping methods to ensure the mapping is correct across all levels
- With no parametric error
  - 16% - 96% runtime reduction for LVS
  - 4% - 49% runtime reduction for ERC
- Tractable method for post-layout timing
- Future work will look at clustering parasitic information
Extra Slides
Motivation: Loss of hierarchy

• **Pre-layout**
  – Lots of hierarchy:
    • Blocks, standard cells, modules

• **Post-layout**
  – Hierarchy flattened due to *layout dependent* parameters
    • Stress, annealing, etch, lithographic variability
  – Netlists 100x-200x larger

• Verification and analysis tools suffer from the lack of hierarchy:
  – Can the hierarchy be recovered?
